20 May 1980

Detailed description of the previous work under this project has been included in the annual and semi-annual reports, for the period 15 March 1977 - 15 May 1979. During that period, analysis was made of selected ultraviolet and visible spectra from the data obtained during two balloon flights made in 1977. A compilation of the best available spectral absorption coefficients data for  $O_3$ ,  $NO_2$ ,  $HNO_2$ ,  $NO_3$  and  $ClO$  has been completed, and used for generating synthetic spectra in the 2800 - 7000 Å region for comparisons with the flight data. With the synthetic spectra atmospheric  $NO_2$  features were identified on the sunset spectra and used for derivation of  $NO_2$  mixing ratio altitude profiles from both flights. The results were described in references 1-3. The present report covers the final period of 15 May 1979 - 15 May 1980.

Data from the 10/10/79 UV balloon flight has been analyzed in an attempt to determine the amount of atmospheric OH. The flight yielded solar spectra at  $\sim 0.05$  Å resolution in the 3060-3090 Å region. Numerous good scans were obtained during ascent and from float altitude ( $\sim 33$  km) during sunset.

The balloon data has been investigated for possible features of atmospheric OH superimposed on the solar OH<sup>(4)</sup> and atomic lines. The expected atmospheric absorptions are quite small,<sup>(5-7)</sup> so the search was conducted by ratioing high sun scans to low sun scans, similar to our work on the  $NO_2$  profiles.<sup>(2)</sup> The low sun scans, however, are

strongly affected by the  $O_3$  attenuation. Optimal filtering<sup>(8)</sup> of the data prior to the ratioing is essential for this work and has been implemented.

Typical spectra obtained during the 10/10/79 flight were presented in the last semiannual report<sup>(9)</sup>. The resolution of the data ( $\sim 0.05 \text{ \AA}$ ) is close to that obtained in the Göttingen atlas,<sup>(10)</sup> which is lower than that obtained in the Kitt Peak atlas.<sup>(11)</sup> The wavelength calibration was done for scan 80 and is based on the Kitt Peak atlas. Wavelength shifts between consecutive scans have been eliminated by cross-correlation programs that were developed for the 1977 UV-visible flights.

Point-by-point ratios of low sun scans to high scans have been formed in the 3070-3085  $\text{\AA}$  region. It is in this region that the strongest features of the  $A^2\Sigma - X^2\Pi(0,0)$  band are expected to occur. These are shown in Figure 1, where OH lines positions (in  $\text{\AA}$ ) and intensities (in  $\text{atm}^{-1}\text{cm}^{-2}$  at 240K) are marked. The line positions and intensities have been generated by Goldman and Gillis.<sup>(12)</sup> Figure 1 and Tables 8, 9 of the paper show the OH line parameters at 240K and 4600K. The complete manuscript is given in the Appendix. The largest atmospheric path achieved before total attenuation by  $O_3$  occurred was with zenith angles of  $\sim 87^\circ$ , corresponding to  $\sim 0.1$  airmass. Examination of these ratioed spectra has failed to reveal any features which can unambiguously be assigned to atmospheric OH. Assuming that we can detect as little as 2% absorption in the ratioed spectrum, an upper limit can

be placed on the vertical column abundance for OH from 33 km altitude of  $\sim 6 \times 10^{12}$  molecules/cm<sup>2</sup>. This is within an order of magnitude of the abundances measured by Anderson<sup>(5)</sup> and Burnett<sup>(6, 7)</sup>.

The estimate of OH abundance from our data is done by considering the weak line approximation, where the equivalent width  $\Delta W$  of a line (or a line group) of intensity  $S$  is given by

$$\Delta W(\text{cm}^{-1}) = S(\text{cm}^{-2} \text{atm}^{-1})N(\text{atm cm}),$$

where  $N$  is the absorber amount.

The strongest feature on our spectrum at the atmospheric temperature of 240K is the partially resolved line group

<u>Transition</u>	<u><math>\lambda(\text{\AA})</math></u>	<u><math>S(\text{cm}^{-2} \text{atm}^{-1})</math></u>
$Q_1(3.5)$	3081.5479	1621
$Q_{P_{21}}(3.5)$	3081.6259	345
$P_1(1.5)$	3081.6677	2060
Total Intensity $S =$		4026

Assuming we can detect 2% absorption and that our resolution is  $0.05 \text{\AA} \approx 0.05 \text{cm}^{-1}$ ,  $\Delta W = (0.02) \times (0.5 \text{cm}^{-1}) = 0.01 \text{cm}^{-1}$ , then the minimum detectable absorber amount is

$$N = \frac{0.01}{4026} = 2.5 \times 10^{-6} \text{ atm cm}$$

$$= 2.5 \times 10^{-6} (\text{atm cm}) \times 2.69 \times 10^{19} (\text{molec/cm}^3) \times \frac{273}{240} \approx 8 \times 10^{13} \text{ molec/cm}^2.$$

The airmass for the scans used (114-118) is  $\sim 0.1$  and at 33 km, the vertical airmass is  $\sim 8 \times 10^{-3}$ , so that the corresponding vertical column is  $\sim 6 \times 10^{12}$ . It is estimated that higher spectral resolution (say,  $\sim 0.01 \text{\AA}$ ) and a more optimal atmospheric path to minimize  $O_3$  absorptions with possibly larger airmass will allow the identification and quantification of OH on such spectra.

Acknowledgment is made to the National Center for Atmospheric Research which is sponsored by the National Science Foundation, for computer time used in this research. Part of the computer programming and analysis was done by Darwin Rolens and James Gillis.

## APPENDIX

SPECTRAL LINE PARAMETERS FOR THE  $A^2\Sigma-X^2\Pi(0,0)$  BAND  
OF OH FOR ATMOSPHERIC AND HIGH TEMPERATURES

Aaron Goldman and James R. Gillis

Department of Physics, University of Denver, Denver, Colorado  
80208, U.S.A.

Abstract - Individual spectral line parameters including line positions, strengths, and intensities have been generated for the  $\Lambda^2\Sigma-X^2\Pi(0,0)$  band of OH, applicable to atmospheric and high temperatures. Energy levels and transition frequencies are calculated by numerically diagonalizing the Hamiltonian. Line strengths are calculated using the dipole matrix and eigenvectors derived from energy matrix diagonalization. The line strengths are compared to those calculated from previously published algebraic line strength formulas. Tables of line parameters are presented for 240 K and 4600 K.

## 1. INTRODUCTION

The  $A^2\Sigma-X^2\Pi(0,0)$  band of OH in the 3085 Å region has been of interest to quantitative spectroscopists for many years because of its high absorption and emission intensity and convenient wavelength location for spectroscopic probes. The hydroxyl radical is a common by-product of most combustion processes, is present in atmospheric, solar and stellar spectra, and in recent years has been also recognized as an important trace constituent in atmospheric chemistry. Accurate determination of the amount of OH present during spectroscopic experiments depends on precise knowledge of line positions and intensities. Several analyses of spectral line positions for this band are available; among the more important of them are those of Dieke and Crosswhite,<sup>1</sup> who provided the first extensive analysis of the OH UV spectrum, and Destombes et al.,<sup>2</sup> who performed elaborate analysis of modern microwave, IR and UV OH data. Intensity (relative and absolute) studies of this band have been reviewed recently by Chidsey and Crosley,<sup>3</sup> who also performed extensive RKR calculations of rotational transition probabilities for the A-X system of OH.

The purpose of this work is to combine the best presently available data and theory to derive accurate quantitative line parameters for the  $A^2\Sigma-X^2\Pi(0,0)$  band, applicable to atmospheric and high temperatures. The results are displayed in line parameter tables, and include improved values for the line strength, calculated in intermediate coupling from the energy matrix eigenvectors.

## 2. LINE PARAMETERS DERIVATION

The OH molecule has an unpaired electron with total electronic angular momentum  $L = 1$  and spin  $S = 1/2$ . In the electronic ground state the projection of  $L$  along the internuclear axis is  $\Lambda = 1$ . The projection of  $S$  along the internuclear axis is  $\Sigma = \pm 1/2$ , with a total electronic angular momentum projection  $\Omega = \Lambda + \Sigma$ . Here,  $\Lambda$ ,  $\Sigma$ ,  $\Omega$  are considered as signed quantities, as in the notation of Hougen.<sup>4</sup> The electronic ground state is an inverted  $^2\Pi$  state with the  $^2\Pi_{1/2}$  ( $\Omega = \pm 1/2$ , F2) levels at higher energy than the  $^2\Pi_{3/2}$  levels ( $\Omega = \pm 3/2$ , F1). The rotational levels for this state are intermediate between Hund's cases (a) and (b). In the  $^2\Sigma$  upper state, which is Hund's case (b),  $\Lambda = 0$  and  $\Omega = \pm 1/2$  with  $J = N \pm 1/2$ . The  $^2\Pi$  and  $^2\Sigma$  states perturb one another resulting in  $\Lambda$  doubling for each  $N$  ( $^2\Sigma_{1/2}$ ) or  $J$  ( $^2\Pi_{1/2, 3/2}$ ).

We use the unique perturber approximation described by Destombes et al.,<sup>2</sup> to calculate energy levels. This process is restricted to a single vibrational level  $v$  in the  $A^2\Sigma - X^2\Pi$  subspace. The total angular momentum number  $F$  is a good quantum number. For a given  $F$ , the  $J$  and  $J+1$  levels are weakly coupled by magnetic hyperfine interactions. These interactions are negligible in the calculation of electronic spectra and  $J$  may be considered a good quantum number. This gives a  $6 \times 6$  Hamiltonian matrix, the elements of which are given in Table 1. The matrix elements are written in Hund's case (a), with the wave functions represented by  $|\Lambda\Sigma\rangle|J\Omega\rangle = |\Lambda\Sigma; J\Omega\rangle$ , so that

$$\begin{aligned}
 ^2\Sigma_{\pm 1/2}^+ : \quad & |\Lambda\Sigma; J\Omega\rangle = |0^+ 1/2 \pm 1/2; J \pm 1/2\rangle \\
 ^2\Pi_{\pm 1/2} : \quad & |\Lambda\Sigma; J\Omega\rangle = |\pm 1 1/2 \mp 1/2; J \pm 1/2\rangle \\
 ^2\Pi_{\pm 3/2} : \quad & |\Lambda\Sigma; J\Omega\rangle = |\pm 1 1/2 \pm 1/2; J \pm 3/2\rangle
 \end{aligned} \tag{1}$$

The Hamiltonian constants used<sup>5</sup> are shown in Table 2 (these constants give a better fit of the observed spectrum than those of Ref. 2, which do not have a sufficient number of digits retained). The 6 x 6 Hamiltonian matrix may be reduced to two 3 x 3 blocks by the Kronig transformation

$$|J\Omega\delta\rangle = \frac{1}{2} (|\Lambda\Sigma\rangle|J\Omega\rangle + \delta|-\Lambda\Sigma\rangle|J-\Omega\rangle), \quad (2)$$

where  $\delta$  equals  $s$  = symmetric = + or  $a$  = antisymmetric = -. In this new basis, one of the 3 x 3 blocks contains only matrix elements of the type  $\langle J'\Omega's|H|J\Omega s\rangle$  and the other contains only matrix elements of the type  $\langle J'\Omega'a|H|J\Omega a\rangle$ .

After numerical diagonalization of a (3 x 3) Kronig transformed block, the electronic state of each eigenvalue (energy level or, more properly, term value in  $\text{cm}^{-1}$ ) may be determined by noting that the largest eigenvalue belongs to the  $^2\Sigma_{1/2}$  state, the intermediate eigenvalue to the  $^2\Pi_{1/2}$  state and the smallest eigenvalue to the  $^2\Pi_{3/2}$  state. The remaining quantum numbers and parities may be determined from Table 3.

The selection rules for  $A^2\Sigma - X^2\Pi(0,0)$  electric dipole allowed transitions are  $\Delta J = 0, \pm 1$ ,  $\Delta N = 0, \pm 1, \pm 2$ . Parity selection rules require  $+\leftrightarrow -$ ,  $+\nleftrightarrow +$ , and  $-\nleftrightarrow -$ , which give wavefunction Kronig symmetry selection rules of  $s\leftrightarrow s$  and  $a\leftrightarrow a$  for  $\Delta J = \pm 1$  (P and R branches) and  $s\leftrightarrow a$  for  $\Delta J = 0$  (Q branches). Transitions are designated by  $^{\Delta N}_{\Delta J} F' F''(J'')$  where ' refers to the upper state and '' refers to the lower state.

These selection rules permit 12 branches, of which 6 are main branches ( $^P_{11}, ^Q_{11}, ^R_{11}, ^P_{22}, ^Q_{22}, ^R_{22}$ ) and 6 are (weaker) satellite branches ( $^Q_{21}, ^R_{21}, ^S_{21}, ^P_{12}, ^Q_{12}, ^O_{12}$ ).

The line intensities  $S_{lu}(T)$  ( $\text{cm}^{-1}/\text{atm cm}$ ) at temperature  $T$  (K) are calculated from<sup>6</sup>

$$S_{lu}(T) = \frac{1}{8\pi c\nu^2} \left( \frac{N}{p} \right) \frac{e^{-1.4388E''/T}}{Q_{VR}} A_{v''J''}^{v'J'} (2J'+1)(1-e^{-1.4388\nu/T}), \quad (3)$$

where  $\nu (=E' - E'')$  is the transition frequency in  $\text{cm}^{-1}$ ,  $c = 2.99792458 \times 10^{10}$  cm/sec,  $N$  is the total number of OH molecules/ $\text{cm}^3$ ,  $p$  is the pressure in atm,  $A_{v''J''}^{v'J'}$  is the Einstein A coefficient in  $\text{sec}^{-1}$ ,  $E''$  is the lower state energy ( $= E_v$ ), and  $Q_{VR}$  is the vibration rotation partition function.

Line intensities may be converted from  $\text{cm}^{-1}/\text{atm cm}$  at  $T$  to cm/molecule at  $T$  by

$$S_{lu}(T)(\text{cm/molecule}) = 3.721963 \times 10^{-20} \frac{T(K)}{273.16(K)} S_{lu}(T)(\text{cm}^{-1}/\text{cm atm}). \quad (4)$$

The  $S_{lu}(T)$  in cm/molecule are at the population temperature.

We assume  $Q_{VR}$  may be given by  $Q_V Q_R$  where the vibrational partition function  $Q_V$  in the harmonic oscillator approximation is

$$Q_V = \frac{1}{1 - e^{-1.4388 \omega_e/T}}, \quad (5)$$

and  $\omega_e$  is the vibrational harmonic oscillator frequency in  $\text{cm}^{-1}$ . Huber and Herzberg<sup>7</sup> give  $\omega_e = 3737.76_1 \text{ cm}^{-1}$ . A comparison of the values of  $Q_V$  calculated by Eq. (5) and by direct summation of  $e^{-E_v/T}$  shows a difference of less than 0.2 percent at 4600 K. The rotational partition function  $Q_R$  is calculated from the actual energy levels as

$$Q_R = \sum_{J''\Omega''} (2J''+1) e^{-1.4388E''(J''\Omega'')/T} \quad (6)$$

Chidsey and Crosley<sup>3</sup> give the Einstein A coefficient as

$$A_{v''J''}^{v'J'} = \frac{64\pi^4}{3h} p_{v''J''}^{v'J'} S_{J'J''} \nu^3 / (2J'+1) \text{ sec}^{-1}, \quad (7)$$

where  $p_{v''J''}^{v'J'}$  is the electronic radial transition probability and  $S_{J'J''}$  is the rotational line strength. Chidsey and Crosley tabulate relative values of  $A_{v''J''}^{v'J'}$  through  $N'' = 32$  for the  $A^2\Sigma - X^2\Pi(0,0)$  band in their Table 4. They state that they calculated the line strengths  $S_{J'J''}$  based on Earls' formulas<sup>8</sup> with a J dependent spin-orbit coupling parameter A and the rotational constants of Dieke and Crosswhite.<sup>1</sup> We have found that use of Earls' formulas can lead to significant errors at high J in the satellite bands (more about this in the following section). Therefore, we have calculated  $S_{J'J''}$  following the method described by Hougen<sup>4</sup> (we describe this in some detail below). Chidsey and Crosley<sup>9</sup> have kindly provided a table of relative  $p_{v''J''}^{v'J'}$  through  $J = 35.5$  prior to publication.

The  $A_{v''J''}^{v'J'}$  may be put on an absolute basis by noting that the lifetime of a state is

$$\tau_{v'J'} = \left( \sum_{v''J''} A_{v''J''}^{v'J'} \right)^{-1} \text{ sec} \quad (8)$$

Because Chidsey and Crosley<sup>3</sup> give  $A_1^0 / A_0^0 = 0.0040$  (here the notation is  $A_{v''}^{v'}$ ), we assume that for the  $v' = 0$  vibrational state all vibrational states other than  $v'' = 0$  make negligible contributions to  $\tau_{v'J'}$ . The

best available lifetime for the rotationless ( $N' = 0$ )  $v' = 0$  state is probably that measured by German,<sup>10</sup>  $\tau_{c,1/2} = (0.688 \pm 0.007) \times 10^{-6}$  sec. There are three transitions from the  $v'' = 0$  state to the rotationless  $v' = 0$  state, namely  $P_{11}$  (1.5),  $P_{12}$  (1.5), and  $P_{012}$  (0.5). We calculate relative  $A_{v''J''}^{v'J'}$  for all  $J'$  and  $J''$  of interest by ignoring all constant factors in Eq. (7) and normalize them using Eq. (8).

We form the  $S_{J',J''}$  following the method given by Hougen.<sup>4</sup> In addition to the selection rules  $\Delta J = 0, \pm 1$  and  $+$   $\leftrightarrow$   $-$  parity, electric dipole selection rules on  $\Omega$  give nonzero matrix elements only for  $\langle \Omega \pm 1 | \mu_x \pm i\mu_y | \Omega \rangle$  for  $\Delta\Omega = \pm 1$  and  $\langle \Omega | \mu_z | \Omega \rangle$  for  $\Delta\Omega = 0$  where  $\mu_x$ ,  $\mu_y$ , and  $\mu_z$  are electric dipole moment components in the molecule fixed axis system. In the laboratory fixed coordinate system

$$\mu_z = \frac{1}{2} (\alpha_{zx} - i\alpha_{zy}) (\mu_x + i\mu_y) + \frac{1}{2} (\alpha_{zx} + i\alpha_{zy}) (\mu_x - i\mu_y) + \alpha_{zz} \mu_z, \quad (9)$$

where  $\alpha_{zx}$ ,  $\alpha_{zy}$ , and  $\alpha_{zz}$  are the direction cosines between the molecule-fixed and laboratory-fixed coordinate systems. The direction cosine matrix elements are given in Table 4. The  $\mu_x$ ,  $\mu_y$ , and  $\mu_z$  are taken to be experimentally determined parameters. For lack of better information, we take  $\frac{1}{2} |\mu_x + i\mu_y| = \frac{1}{2} |\mu_x - i\mu_y| = |\mu_z| = 1$ , i.e., the electronic perpendicular and parallel transition moments are equal (see below).

Because we assume the electronic and rotational parts of the wavefunction are separable, the electric dipole matrix elements may be written as

$$\begin{aligned}
& \langle \Lambda' S' \Sigma'; J' \Omega' | \mu_z | \Lambda S \Sigma; J \Omega \rangle \\
&= \frac{1}{2} \langle \Lambda' S' \Sigma' | \mu_x + i \mu_y | \Lambda S \Sigma \rangle \langle J' \Omega' | a_{zx} - i a_{zy} | J \Omega \rangle \\
&+ \frac{1}{2} \langle \Lambda' S' \Sigma' | \mu_x - i \mu_y | \Lambda S \Sigma \rangle \langle J' \Omega' | a_{zx} + i a_{zy} | J \Omega \rangle \\
&+ \langle \Lambda' S' \Sigma' | \mu_z | \Lambda S \Sigma \rangle \langle J' \Omega' | a_{zz} | J \Omega \rangle, \quad (10)
\end{aligned}$$

where " has been dropped on the lower state quantities. Only one of the three terms in the right hand side of Eq. (10) is nonzero for any allowed transition matrix element. The electric dipole transition matrix is formed in the same basis as was the Hamiltonian matrix, that is, the Hund's case (a) basis. Selection rules in this basis are  $\Delta S = 0$ ,  $\Delta \Sigma = 0$ ,  $\Delta \Lambda = 0, \pm 1$ , and  $\Delta J = 0, \pm 1$ . Because  $\Delta \Sigma = 0$  and  $\Omega = \Lambda + \Sigma$ , the selection rule  $\Delta \Omega = \Delta \Lambda$  is obtained. As we are interested in  $\Sigma - \Pi$  transitions, we set all matrix elements of the type  $\langle \Sigma | \mu_z | \Sigma \rangle$  and  $\langle \Pi | \mu_z | \Pi \rangle$  to zero. The relative phases of the matrix elements are determined by following the prescription of Hougen<sup>4</sup> and Whiting and Nicholls.<sup>11</sup> Following the suggestions of Whiting and Nicholls, we have normalized the line strengths so that

$$\sum_{\Sigma, J'} S_{J' J''} = 2(2S + 1)(2J'' + 1) = 4(2J'' + 1), \quad (11)$$

Table 4 reflects this choice of normalization.

The line strength  $S_{J' J''}$  is formed in intermediate coupling by taking  $|\langle u | \mu_z | l \rangle|^2$  where  $|u\rangle$  represents the eigenvector of the  $\Sigma$  state,  $|l\rangle$  represents the eigenvector of the  $\Pi$  state and  $\mu_z$  now represents the  $6 \times 6$  transition matrix. However, the eigenvectors formed during the diagonalization of the energy matrices are in the Kronig transformed basis; therefore, the dipole matrix must also be transformed into this basis. Using the Kronig transformed wavefunctions given by Eq.(1), the Kronig transformed dipole matrix elements have the form

$$\begin{aligned}
& \langle J' \Omega' \delta' | \mu_Z | J \Omega \delta \rangle \\
&= \frac{1}{2} \{ \langle J' \Omega' | \mu_Z | J \Omega \rangle + \delta \langle J' \Omega' | \mu_Z | J - \Omega \rangle \\
&+ \delta' \langle J' - \Omega' | \mu_Z | J \Omega \rangle + \delta \delta' \langle J' - \Omega' | \mu_Z | J - \Omega \rangle \} \quad , \quad (12)
\end{aligned}$$

and, if we let  $\mu_Z^K$  be the matrix of the  $\langle J' \Omega' \delta' | \mu_Z | J \Omega \delta \rangle$ ,

$$S_{J' J''}^{Q_1} = |\langle J' \Omega' \delta' | \mu_Z^K | J \Omega \delta \rangle|^2. \quad (13)$$

To our knowledge the  $\Sigma - \Pi$  transition matrices have not been published elsewhere. We show them for the P, Q, and R branches in Tables 5 through 7. The twelve branches correspond to the four (3x3) blocks in the Kronig basis as follows

$$\left( \begin{array}{c|c} \begin{array}{c} a \leftarrow a \\ P_{P11}, R_{R11}, O_{P12}, Q_{R12} \end{array} & \begin{array}{c} a \leftarrow s \\ Q_{Q11}, P_{Q12} \end{array} \\ \hline \begin{array}{c} s \leftarrow a \\ Q_{Q22}, R_{Q21} \end{array} & \begin{array}{c} s \leftarrow s \\ P_{P22}, R_{R22}, Q_{P21}, S_{R21} \end{array} \end{array} \right) \quad (14)$$

For Q-branch lines, the only non-zero (3x3) blocks are the  $a \leftarrow s$  and  $s \leftarrow a$ , while for R- and P-branch lines, the only nonzero (3x3) blocks are the  $a \leftarrow a$  and  $s \leftarrow s$ . When forming line strengths, the appropriate block must be substituted into Eq. (13) for  $\mu_Z^K$ . For example, to generate the  $Q_1$  line strength we form

$$S_{J' J''}^{Q_1} = \left| \langle \psi_{2\Sigma_{1/2}}^a | (a \leftarrow s) | \psi_{2\Pi_{3/2}}^s \rangle \right|^2. \quad (15)$$

### 3. RESULTS AND DISCUSSION

Line strengths, Einstein A coefficients, intensities, and transition frequencies have been calculated for all branches of the  $A^2\Sigma-X^2\Pi(0,0)$  OH spectrum through  $J = 15.5$  at 240 K for atmospheric applications and through  $J = 40.5$  at 4600 K for high temperature applications. These calculated values are shown in Tables 8 and 9, respectively. The total band intensities (by summation of the individual lines) are  $2.7948 \times 10^4 \text{ cm}^{-1}/\text{atm cm}$  at 240 K and  $8.6863 \times 10^2 \text{ cm}^{-1}/\text{atm cm}$  at 4600 K. Line intensities are plotted at these two temperatures in Fig. 1. Some caution must be exercised in using high J data from Table 9. The spectroscopic constants<sup>5</sup> used here were determined from data<sup>2</sup> which included transitions through  $J = 25.5$ . Although these constants allow prediction of that data to within  $0.1 \text{ cm}^{-1}$  maximum error and a standard deviation of  $\sim 0.03 \text{ cm}^{-1}$  (hyperfine structure is neglected here), such accuracy cannot be expected for all lines between  $J = 25.5$  and 40.5. Uncertainties in the calculation of energy levels at these high J cause proportionally smaller uncertainties in the energy eigenvectors (wavefunctions) and in quantities calculated using the eigenvectors (line strengths, Einstein A coefficients, and intensities).

Chidsey and Crosley<sup>9</sup> list  $p_{v''J''}^{v'J'}$  through  $J = 35.5$ . We have extrapolated  $p_{v''J''}^{v'J'}$  for  $J = 36.5$  through 40.5. Although the dependence of  $p_{v''J''}^{v'J'}$  on J is quite linear for P, Q, and R transition probabilities between  $J = 25.5$  and 35.5, extrapolated  $p_{v''J''}^{v'J'}$  used to calculate Einstein A coefficients and intensities at higher J must be used with caution.

Although we list four digits for Einstein A coefficients and intensities in Tables 8 and 9, the absolute uncertainties of these quantities cannot be less than 1 percent, because German's<sup>10</sup>  $\tau_{0,1/2}$  has a 1 percent quoted uncertainty and because Chidsey and Crosley's<sup>9</sup>  $p_{v''J''}^{v'J'}$  are quoted to three significant

digits. The relative uncertainties are limited by the relative accuracy of the  $p_{v''J''}^{v'J'}$  and the line strengths. These relative uncertainties should be less than 0.5 percent for  $J$  less than 25.5 and are probably less than one percent for  $J$  less than 35.5. It should be noted that the present results are based on the assumption that the magnitudes of the parallel and perpendicular electronic transition moment components are equal. To check this assumption we calculated oscillator strengths  $f_{\ell \rightarrow u}$  according to Penner's<sup>6</sup> Eq. (2-21) and compared them to the tabulated values of Sutherland and Anderson.<sup>12</sup> We found no differences between the two sets of  $f_{\ell \rightarrow u}$  significant enough to indicate that the magnitudes of the parallel and perpendicular electronic transition moment components are different.

Our calculated line strengths have been checked for accuracy by comparison with the values calculated using Earls'<sup>8</sup> algebraic formulas (these formulas are equivalent to those of Kovacs<sup>13</sup> for  $\Sigma \rightarrow \Pi$  transitions). When centrifugal and higher order distortion and  $\Sigma \rightarrow \Pi$  interactions are ignored, our line strengths are identical to those calculated using Earls' formulas. Ignoring these effects does not significantly alter the line strengths for main branch transitions, but does lead to large errors at high  $J$  for the weaker satellite branch line strengths. Earls' formulas (which ignore centrifugal and higher distortion and  $\Sigma \rightarrow \Pi$  interactions) predict consistently smaller line strengths than those calculated by us (which include centrifugal and higher distortion and  $\Sigma \rightarrow \Pi$  interactions). In the  $Q_{R_{12}}$  branch, Earls' line strengths range from 93 percent of our line strength at  $J'' = 20.5$  to 69 percent of our line strength at  $J'' = 40.5$ ; in the  $S_{R_{21}}$  branch they range from 78 percent of our line strength at  $J'' = 20.5$  to 46 percent of our line strength at  $J'' = 39.5$ . Earls' formulas show errors intermediate in this range for the other satellite branches.

Bennett's<sup>14</sup> line strength formulas, which include  $P^4$  centrifugal distortion, may be expected to give much more accurate results. Based on our

check of Earls' formulas, the line strengths for the  $S_{R_{21}}$  branch should have the largest deviation. Bennett's formula predicts line strengths for this branch which are 1 percent high at  $J = 1.5$ , decreasing to 6 percent low at  $J = 25.5$ , and increasing to 2 percent high at  $J = 39.5$ . Examination of the eigenvectors shows that the  $P^6$  term, and, to a lesser extent, the  ${}^2\Sigma - {}^2\Pi$  mixing, can contribute an effect of a few percent to the satellite bands line strengths. Thus, the dominant effect in the deviations from Earls' formulas is due to the centrifugal distortion, which is relatively large in a light molecule such as OH.

The conclusion to be drawn from these comparisons is that both the algebraic formulas or our method give accurate main branch line strengths at all experimentally observed  $J$  values. Earls' formulas lead to significant errors at high  $J$  in the satellite bands. Bennett's formulas give acceptable satellite branch line strengths for most work. However, when highest accuracy is required, the line strengths from Table 9 should be used.

When our Einstein A coefficients are normalized to the same relative value as those of Chidsey and Crosley,<sup>3</sup> the two sets of values differ by at most  $\pm 2$  in the last decimal place. As with the line strengths, these differences become important only at high  $J$  in the satellite branches where many of the relative Einstein A coefficients are quoted to only one significant digit by Chidsey and Crosley. An additional advantage of our Einstein A coefficients in Tables 8 and 9 for quantitative spectroscopy is that they are absolute rather than relative values.

Although we have chosen to present OH line parameters for temperatures of 240 K and 4600 K, our computer program can generate  $A \Sigma - X \Pi(0,0)$  band line parameters for any temperature. Table 10 may be used with Table 8 or 9 and Eq.(3) and (5) to convert line intensities from these temperatures to any temperature in the 200 - 6000 K range. Intensities so determined should have the

same accuracy as those in Tables 8 and 9. Band intensities at temperatures other than 240 K and 4600 K may be calculated by summing the individual line intensities at the desired temperature. Simpler approximate procedures which directly convert from a band intensity at one temperature to a band intensity at another temperature such as Eq. (7-126) in Penner<sup>6</sup> give errors of approximately 15 percent when band intensities at 240 K and 4600 K are compared.

Acknowledgments - This research was supported in part by NASA/Langley contract NSG 1405. We thank J.L. Destombes and C. Marliere-Demuynck for kindly providing molecular constants which predict the line positions better than those previously published, and I.L. Chidsey and D.R. Crosley for kindly providing tables of  $p_{v''j''}^{v'j'}$  prior to their scheduled publication. Acknowledgment is made to the National Center for Atmospheric Research, which is sponsored by the National Science Foundation, for computer time used in this research.
